

CS 11 Data Structures and Algorithms

Assignment 6: Dynamic Memory in Classes 2

[Skip to Main Content](#)

Learning Objectives

After the successful completion of this learning unit, you will be able to:

- Define syntactically correct classes that use dynamic memory in accordance with good programming practice
- Explain the "Big-three" member functions that are required when a class uses dynamic memory.

Assignment 6.1 [45 points]

See also **client program**, **data file**, and **correct output**.

This week you'll be making the following refinements to the class that you wrote in the last assignment. All the requirements from that class still apply. For example, all MyStrings must always be stored in a dynamic array that is exactly the correct size to store the string.

Extraction Operator [10 points]

Just like the `>>` operator that reads C-strings, your `>>` operator should skip any leading spaces and then read characters into the string up to the first whitespace character.

For reasons of convenience, we will impose a limit of 127 on the number of characters this function will read. This is so you can temporarily read into a non-dynamic array and then copy what you need into your data member, which will be a dynamic array. Note that this does not mean that all MyStrings will always have a maximum of 127 characters. For example, you might get a MyString with more than 127 characters by using the MyString constructor or by concatenating two MyStrings.

Hint: Don't try to read character by character in a loop. Use the extraction operator to do the reading of the input into a non-dynamic array, then use `strcpy()` to copy it into your data member. Make sure to allocate the correct amount of memory.

Hint: if you use the extraction operator as suggested above, you will not have to skip leading whitespace, because the extraction operator does that for you.

A read() function [10 points]

The `read()` function will allow the client programmer to specify the delimiting character (the one to stop at instead of the first space). This will be a void function that will take two arguments, a stream and the delimiting character. It should not skip leading spaces. The limit of 127 characters imposed on the `>>` function above also applies to this function.

Hint: Don't try to read character by character in a loop. Use the `in.getline()` function to do the reading of the input into a non-dynamic array, then use `strcpy()` to copy it into your data member.

Concatenation Operator [10 points]

Overload the `+` operator to do MyString concatenation. The operator must be able to handle either MyString objects or C-strings on either side of the operator. Be careful with the memory management here. You'll have to allocate enough memory to hold the new MyString. I suggest using `strcpy()` to get the left operand into the result MyString, and then `strcat()` to append the right operand. Both `strcpy()` and `strcat()` should be used as if they are void, even though they do have return values.

Combined Concatenation/Assignment Operator [5 points]

Overload the shorthand `+=` to combine concatenation and assignment. Only MyStrings can be on the left-hand side of a `+=` operation, but either MyStrings or C-strings may appear on the right side. If you pay close

attention to the += operator from the feetInches class, these may be the easiest points of the semester.

Add Documentation [10 points]

Hints about reading input files:

I suggest that you copy the text from the input file webpage and paste it into a file that you have created using your IDE. The files you create when you type in your IDE are always text files (even if they don't end with .txt). If you're using Windows, you could also use Notepad, but there's no reason to open another application when you are already working in your IDE. I strongly suggest that you don't use TextEdit (Mac) or Word, because these do not store files as text files by default.

Here is **important information about where to save your input file so that your IDE can find it**

Extensions are part of the file name. If you want read from a file named "myfile.txt", typing "myfile" or "myfile.cpp" won't work.

For Windows users, before you start this assignment, I suggest that you make sure that Windows is showing you the complete file name of your files, including the extensions. Windows hides this from you by default. In Windows 7 and 8 the procedure is as follows:

1. Choose "control panel" from the start menu
2. Choose "Folder Options" from the list of control panel items. In Windows 8 you may have to type "Folder Options" into the control panel search bar.
3. Choose the "view" tab from the Folder Options window
4. Find the checkbox that says "Hide extensions for known file types".
5. Uncheck that checkbox.

In Windows 10 the procedure is: go to file explorer and click "View" on the toolbar, then go to "Options" on the furthest right, click on the drop down arrow and choose "Change folder and search options". Click "View" on the top and uncheck "Hide extensions for known file types"

Submit Your Work

Name your source code file(s) mystring.cpp and mystring.h. Execute the given client program and copy/paste the output into the bottom of the implementation file, making it into a comment. Use the Assignment Submission link to submit the source file(s). When you submit your assignment there will be a text field in which you can add a note to me (called a "comment", but don't confuse it with a C++ comment). In this "comments" section of the submission page let me know whether the program(s) work as required.
